

1) Non-stationary and transient condition (e.g., exercise).

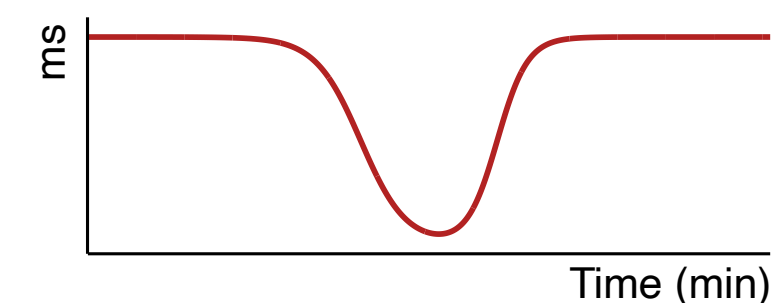

R-R detection from ECG signal.

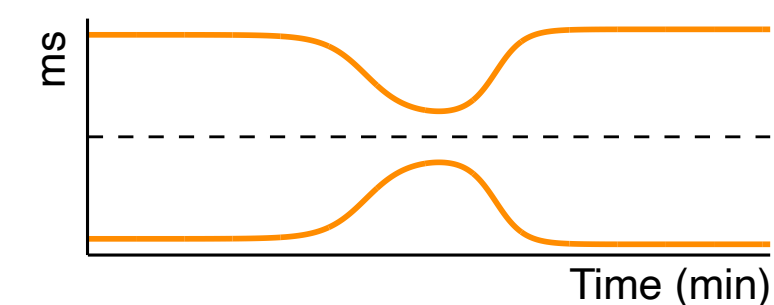

Conversion to R-R Interval Data.

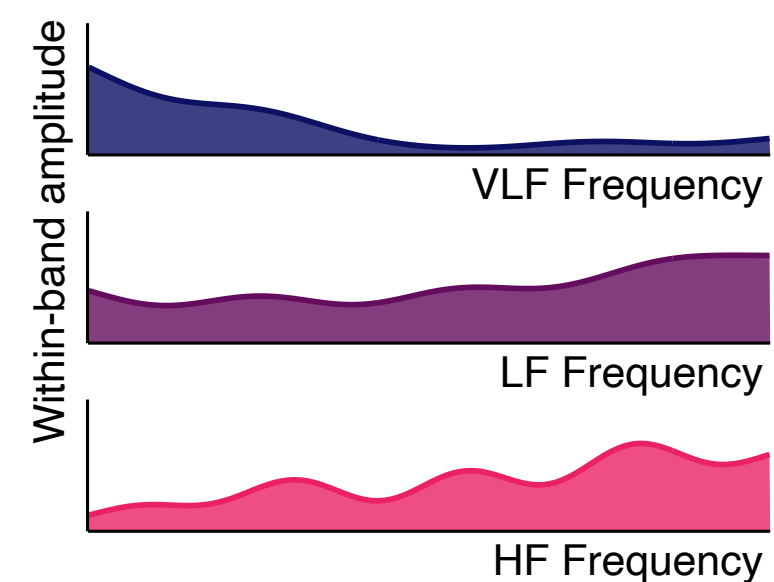

2) Recording and collection of R-R interval data.

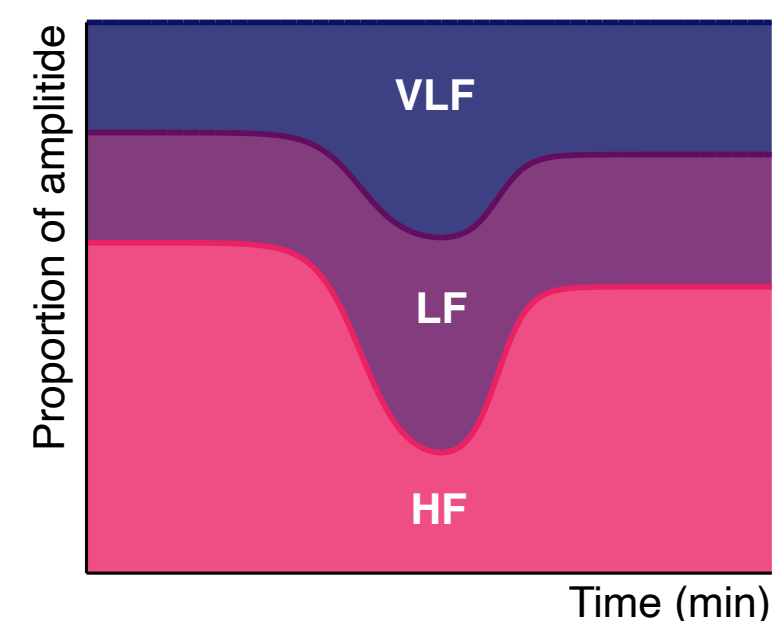

Gross underlying R-R interval trajectory.

Band amplitude, describes signal variability.

Base spectral composition, unique for each individual.

Temporal evolution of the relative participation of each frequency band.

3) Application of the **B**iphasic **A**utonomic **N**on-stationary **D**ecomposition (BAND) model.
